## Summary description

Used to control gathering for traces exiting a round pin or via while concurrently routing more than one net (e.g. differential pair). The purpose is to allow the traces to gather sooner. The value is used as a percentage to reduce the minimum clearance that the gathering code requires between the pin/via and the second segment of the cline exiting the pad. By default, it requires 100 percent of the applicable minimum segment to pin/via spacing constraint. A value of 75 causes the minimum space to be 75 percent of the constraint set value.
